

Figure 1. Forest cover change between 2015-2024 around a 900-acre carbon project property (red outline), as provided by the Landscape Change Monitoring System (LCMS), a remote sensing-based system for mapping and monitoring landscape change across the United States. Large-scale timber harvesting (identified here as bright green ‘tree removal’ or lavender ‘other loss’) is the primary driver of forest cover loss over this period. Forest cover loss within the project property itself occurred prior to the carbon project start date.
